ARE TESTS OVERRATED?

Optimizing Health Policies

Malaria and Pneumonia in Sub-Saharan Africa

Introduction

Your Hosts Today

- Stefan Conrady
  stefan.conrady@bayesia.us

- Stacey Blodgett
  stacey.blodgett@bayesia.us

Today's Objectives

Methodological Objective

- Bayesian networks as a framework for reasoning about health policies under uncertainty.

Substantive Research Objective

- Establish optimal policies for malaria and pneumonia diagnosis and treatment, i.e., "Test & Treat" vs. Presumptive Treatment.

Today's Agenda

Motivation & Background

- Over- and Undertreatment Malaria and Pneumonia
- Testing Innovations & WHO Guidelines

Methodology

- Knowledge Modeling & Reasoning with Bayesian Networks

Research Workflow

- Encode Domain Knowledge in Bayesian Network
- Elicit Probabilities
- Assess Costs and Utilities
- Search for Optimal Policies

"Test and treat" or presumptive treatment for malaria in high transmission situations? A reflection on the latest WHO guidelines

Bertrand Graz[1*], Merlin Willcox[2], Thomas Szeless[1] and André Rougemont[1]

Abstract

Recent WHO guidelines recommend a universal "test and treat" strategy for malaria, mainly by use of rapid diagnostic test (RDT) in all areas. The evidence for this approach is questioned here as there is a risk of over-reliance on parasitological diagnosis in high transmission situations, which still exist. In such areas, when a patient has fever or other malaria symptoms, the presence of *Plasmodium* spp neither reliably confirms malaria as the cause of the fever, nor excludes the possibility of other diseases. This is because the patient may be an asymptomatic carrier of malaria parasites and suffer from another disease.

To allow clinicians to perform their work adequately, local epidemiologic data are necessary. One size all. If parasite prevalence in the population is low, a diagnostic test is relevant; if the prevalence is does not provide information of any clinical usefulness, as happens with any test in medicine w of the tested characteristic is high in the healthy population. It should also be remembered that, anti-malarials are prescribed to parasite-negative patients, this will not increase selection pressure fo resistance, because the parasite is not there.

In high transmission situations at least, other diagnoses should be sought in all patients, irrespective of th presence of malaria parasites. For this, clinical skills (but not necessarily physicians) are irreplaceable, in order differentiate malaria from other causes of acute fever, such as benign viral infection or potentially dangerous conditions, which can all be present with the parasite co-existing only as a "commensal" or silent undesirable guest.

Background

The latest WHO guidelines on the treatment of malaria state that, whenever possible, "*in all settings, clinical suspicion of malaria should be confirmed with a parasitological diagnosis*" [1,2]. This is a significant change

settings, which still exist. Basically, the « level of transmission » in malarial areas is an entomological concept. In most cases, the so-called transmission level is derived from the proportion of infected people in the general population. For practical purposes, it is consid-

Multi-method assessment of patients with febrile illness reveals over-diagnosis of malaria in rural Uganda

Ria R. Ghai[1,2*], Mary I. Thurber[3], Azza El Bakry[4], Colin A. Chapman[5,6,7] and Tony L. Goldberg[6,8]

Abstract

Background: Health clinics in rural Africa are typically resource-limited. As a result, many patients presenting with fever are treated with anti-malarial drugs based only on clinical presentation. This is a considerable issue in Uganda, where malaria is routinely over-diagnosed and over-treated, constituting a wastage of resources and an elevated risk mortality in wrongly diagnosed patients. However, rapid diagnostic tests (RDTs) for malaria are increasingly being health facilities. Being fast, easy and inexpensive, RDTs offer the opportunity for feasible diagnostic capacity in limited areas. This study evaluated the rate of malaria misdiagnosis and the accuracy of RDTs in rural Uganda, presumptive diagnosis still predominates. Specifically, the diagnostic accuracy of "gold standard" methods, PCR, were compared to the most feasible method, RDTs.

presenting with fever at one of two health clinics in the Kabarole District of Uganda were enrolled d was collected by finger prick and used to administer RDTs, make blood smears for microscopy, man FTA cards for DNA extraction, polymerase chain reaction (PCR) amplification, and sequencing. The RDTs and microscopy were assessed relative to PCR, considered the new standard of malaria diagnosis.

s: A total of 78 patients were enrolled, and 31 were diagnosed with *Plasmodium* infection by at least one hod. Comparing diagnostic pairs determined that RDTs and microscopy performed similarly, being 92.6 and 2.0 % sensitive and 95.5 and 94.4 % specific, respectively. Combining both methods resulted in a sensitivity of 96.0 % and specificity of 100 %. However, both RDTs and microscopy missed one case of non-falciparum malaria (*Plasmodium malariae*) that was identified and characterized by PCR and sequencing. In total, based on PCR, 62.0 % of patients would have been misdiagnosed with malaria if symptomatic diagnosis was used.

Conclusions: Results suggest that diagnosis of malaria based on symptoms alone appears to be highly inaccurate in this setting. Furthermore, RDTs were very effective at diagnosing malaria, performing as well or better than microscopy. However, only PCR and DNA sequencing detected non-*P. falciparum* species, which highlights an important limitation of this test and a treatment concern for non-falciparum malaria patients. Nevertheless, RDTs appear the only feasible method in rural or resource-limited areas, and therefore offer the best way forward in malaria management in

?

Optimizing Health Policies

Caveat

- The medical subject matter presented in this webinar is strictly for methodological illustration purposes.
- Today's particular problem domain of infectious disease diagnosis is merely a prototypical example diagnostic inference.
- Also, the subject matter is presented in a highly simplified format. This is by no means an exhaustive treatment of the topic.
- No part of this webinar should be interpreted as medical research or a health policy recommendation.

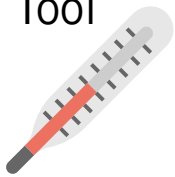
Motivation & Background

Infectious Diseases in Sub-Saharan Africa

- 4.2 million annual child deaths
- Over 1 million due to bacterial pneumonia
- Over 750,000 due to malaria

Similar Symptoms

Diagnostic Tool



Economical, efficacious treatments are available:
- Antibiotics for bacterial pneumonia
- Artimisinin-combination therapies (ACT) for malaria

Pneumonia Diagnosis in the Developed World

Radiography

  - 200,000 Rapid Diagnostic Tests (RDT) distributed in 2005
  - 50 million in 2010

LONDON SCHOOL of HYGIENE &TROPICAL MEDICINE

Rapid diagnostic tests linked to improved targeting of antimalarial drugs, but more antibiotic prescriptions

8 August 2017

Unintended Consequences

- "The researchers found that after the rapid diagnostic test ruled out malaria, many patients were prescribed antibiotics — in effect, **trading the overuse of anti-malarial drugs for the overuse of antibiotics**."
- "'If you're in a remote area and you don't have a lot of other options — you've got a sick child or a sick patient in front of you, that person may have come from even up to 20 kilometers away with expensive transport or even walking — you want to do something,' Hopkins says. 'And if you don't feel like you should give an anti-malarial — the test is negative — your alternative, in some cases, is an antibiotic.'"

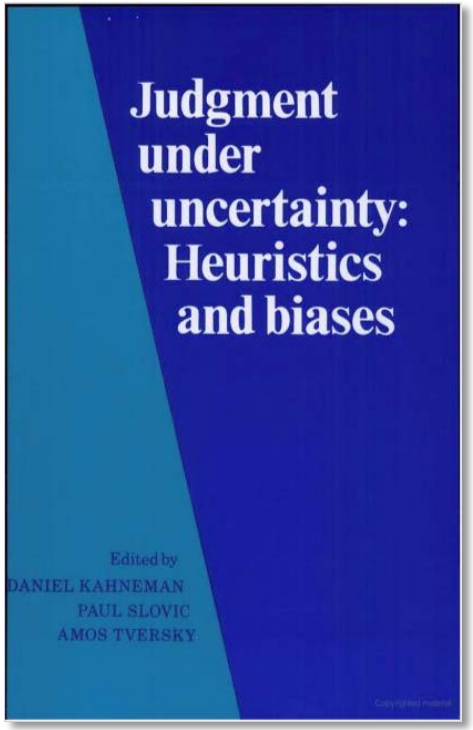
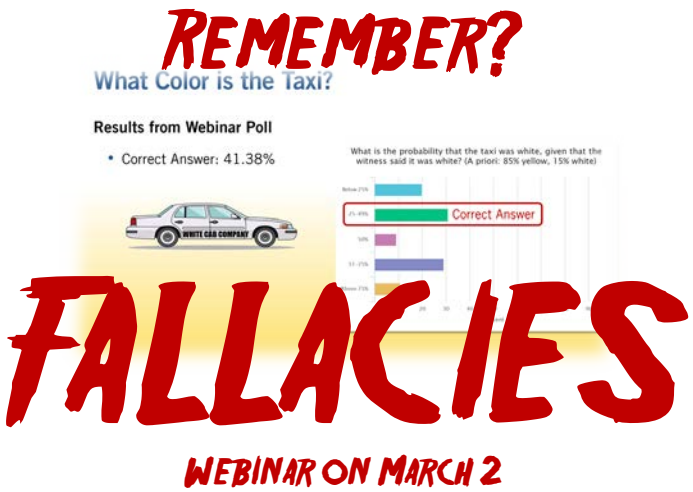
Probabilistic Reasoning

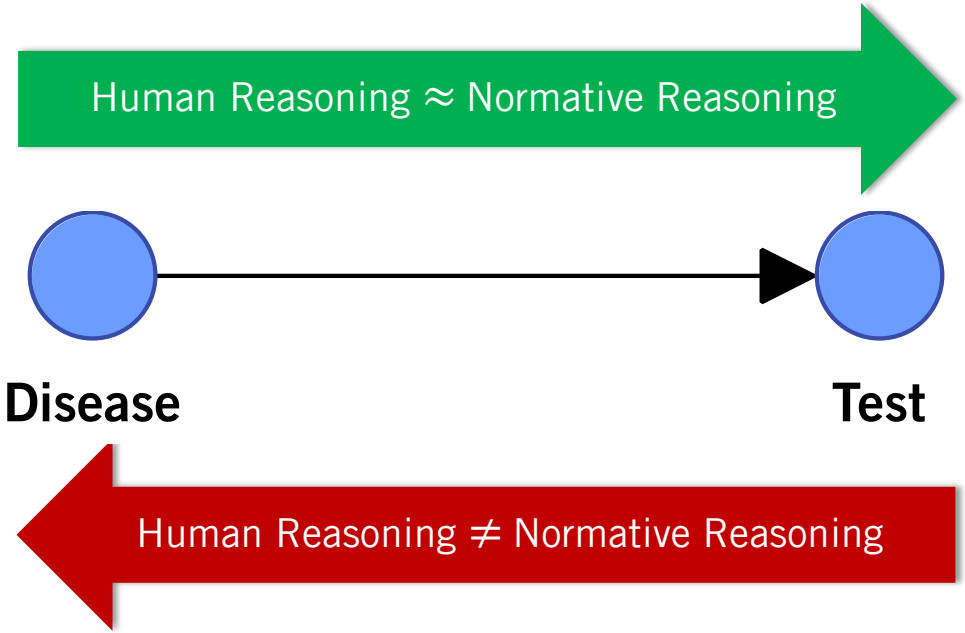
Human reasoning is flawed!



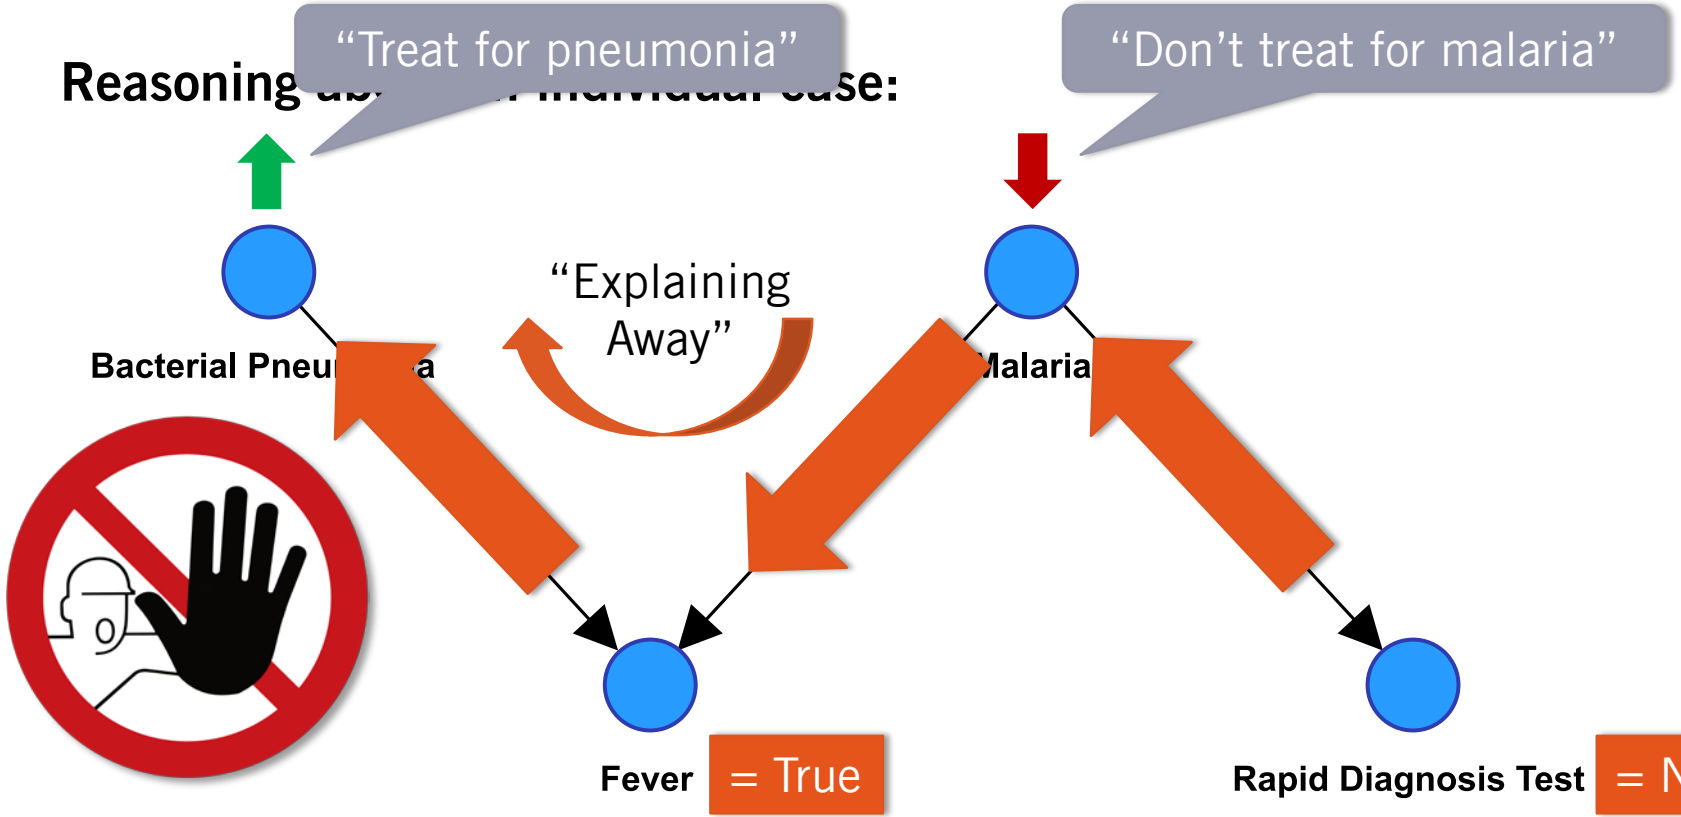
Probabilistic Reasoning

Human Cognitive Limitations and Biases Under Uncertainty





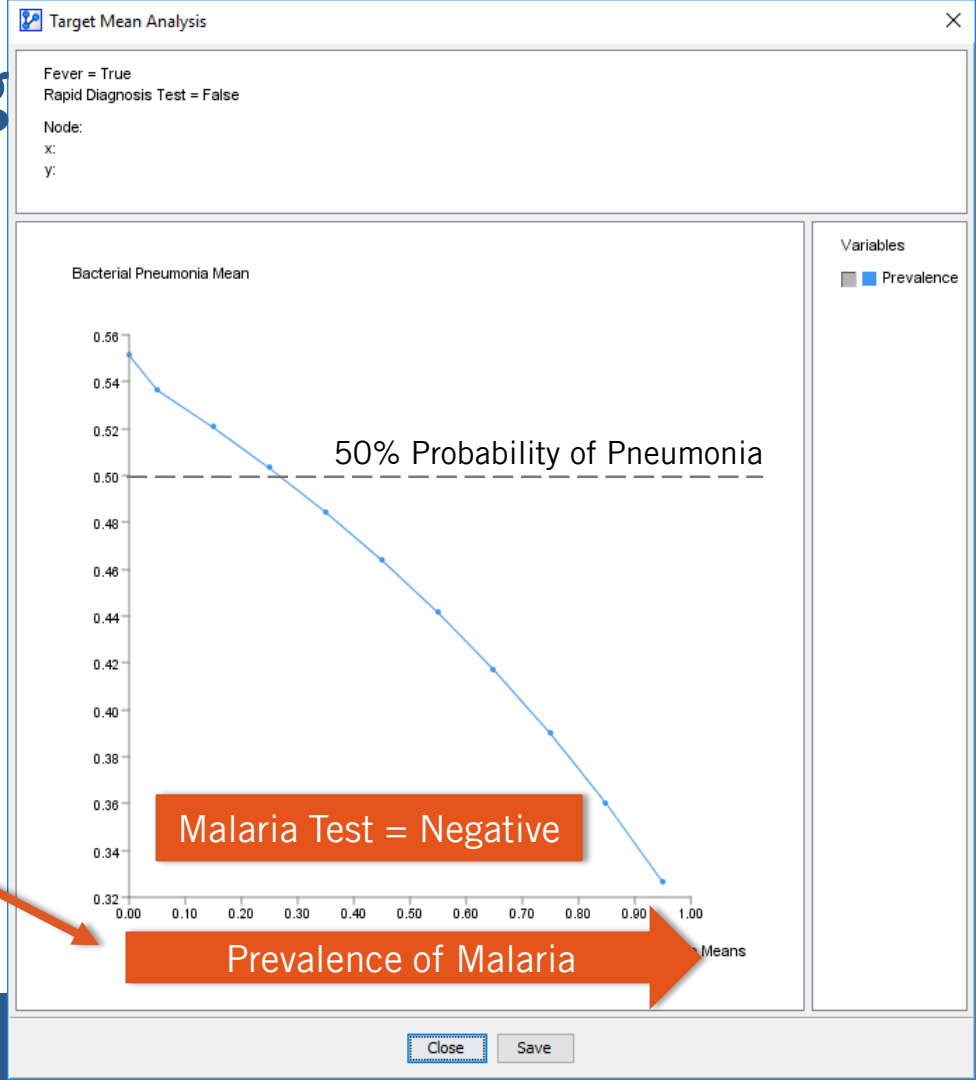
Probabilistic Reasoning



Probabilistic Reasoning

Why Not?

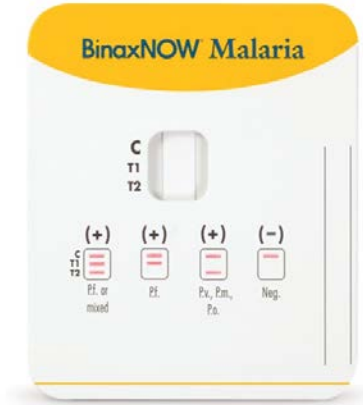
- The probability of pneumonia given a negative malaria test result depends on:
  - Prevalence of pneumonia
  - Sensitivity & Specificity of RDT
  - Prevalence of malaria



New Health Policy?

Hypothetical Example

Testing for Malaria and Pneumonia?



&

Rapid Diagnosis Test for Malaria

C-reactive protein (CRP) Test for Pneumonia

New Health Policy?

Policy Questions

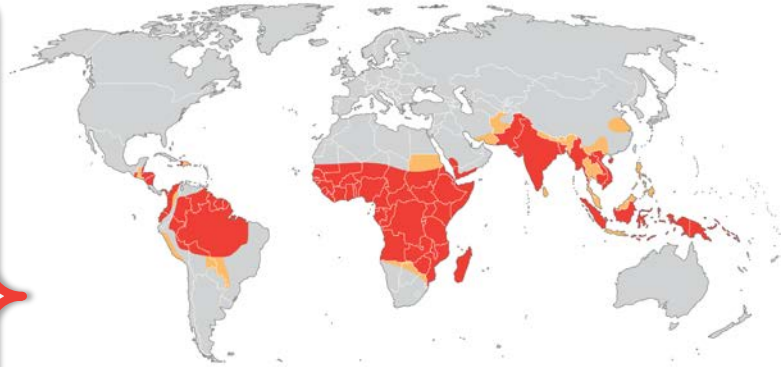
- For Malaria
    - Test & Treat **or** Presumptive Treatment
- For Bacterial Pneumonia
    - Test & Treat **or** Presumptive Treatment

New Health Policy?

Hypothetical Example

Additional Considerations for New Guidelines

- Cost of tests
- Cost of treatments
- Limited resources
- Efficacy of treatments
- Unintended consequences of overtreatment, e.g., antibiotics resistance
- Adherence to protocols
- Prevalence of diseases
- Comorbidities
- Regional factors, e.g., climate, seasonality



If it is difficult to reason about a single case, how can we establish a policy for the world?
